Service: payment-service
Severity: CRITICAL

Incident Report: anomaly_payment-service_1779356982

Service: payment-service
Detected: 2026-05-21T09:49:42.324146
Severity: CRITICAL
Model confidence: 0.95

Executive summary

The payment-service is experiencing a critical degradation characterized by a significant spike in latency and a high volume of database timeout errors. This incident is currently impacting service reliability with an error rate of approximately 50.5%.

Root cause hypothesis

The payment-service is suffering from a database-level bottleneck, as evidenced by the high error_count and frequent 'DB timeout' log entries. The p99_latency_ms spike to 6430.812ms and the high latency_std indicate that requests are queuing or timing out while waiting for database resources, leading to the observed 50.5% error rate.

Top contributing features (SHAP)

Feature	Value	SHAP	Direction
p99_latency_ms	6430.812	-1.722	toward_anomaly

Feature	Value	SHAP	Direction
error_count	147.000	-1.593	toward_anomaly
latency_std	2305.044	-1.496	toward_anomaly

Recommended actions

Immediate

- **Check database connection pool health and active transaction logs.** - The presence of 'DB timeout' log entries and high p99_latency_ms suggests the service is struggling to communicate with the database backend.

Short Term

- **Review recent database schema changes or query deployments.** - The high latency_std and elevated error_count indicate a sudden instability in request processing, often caused by inefficient queries or lock contention.

Long Term

- **Implement circuit breakers for database-dependent operations.** - To prevent cascading failures when the database becomes unresponsive, as evidenced by the current 50.5% error rate.
